Problem 1: Matrices in R

In R, matrices are constructed using the function matrix(). This function accepts different options. We want to see, how these options work.

Your Task: Construct matrices using the different options to better understand the meaning of the different options.

Parameter data

• data: Specify the different matrix elements

```
(matA <- matrix(data = c(1:9), nrow = 3, ncol = 3))</pre>
```

• data: without specifying the matrix elements

```
(matB <- matrix(nrow = 3, ncol = 3))</pre>
```

• data: specifying not all matrix elements

```
(matC <- matrix(data = c(1,2,3), nrow = 3, ncol = 3))
(matC2 <- matrix(data = c(1,2,3,4), nrow = 3, ncol = 3))</pre>
```

Parameters nrow and ncol

• Leaving out one of both parameters

```
(matD <- matrix(data = c(1:9), nrow = 3))
(matE <- matrix(data = c(1:9), ncol = 3))</pre>
```

Parameter byrow

```
(matF <- matrix(data = c(1:9), nrow = 3, ncol = 3, byrow = TRUE))
(matG <- matrix(data = c(1:9), nrow = 3, ncol = 3, byrow = FALSE))</pre>
```

Problem 2: Matrix multiplication in R

In R, matrices can be multiplied using the operator %*% or with the functions crossprod() or tcrossprod(). With crossprod() and tcrossprod() vectors and matrices can be multiplied directly. The conversion of vectors to matrices is done automatically inside of these functions. The result will always be a matrix. When doing matrix-vector multiplications with %*% the vector has to be converted first into a matrix using the function as.matrix().

In a first part of this problem, compare the results of the functions crossprod(), tcrossprod() and %*%.

a) Given are the following matrices

```
matA <- matrix(data = c(1:9), ncol = 3)
matB <- matrix(data = c(2:10), ncol = 3)</pre>
```

Find out which matrix multiplication with %*% corresponds to the following statement?

```
crossprod(matA,matB)
```

Alternatively there is the function tcrossprod(). Find out which matrix multiplication is executed by tcrossprod(matA, matB)

b) Given is the vector vecB

```
vecB <- c(-3,16,1)
```

Multiply the matrix matA with the vector vecB once using %*% and then with the function crossprod().

Hint: a vector can be converted to a matrix using the function as.matrix().

Problem 3: Quantitative Genetics

In a population the following numbers of genotypes were counted for a given genetic locus called A.

Genotypes	Numbers
$\overline{A_1A_1}$	24
A_1A_2	53
A_2A_2	23

- a) Compute the genotype frequencies
- b) Compute the allele frequencies
- c) Compute the population mean μ under the following assumptions
- the difference between the genotypic values of the homozygous genotypes is 20 and
- the genotypic value of the heterozygous genotype is 2.
